Project Abstract

Neha Malhan (T00757554) & Thiwanka Abeyweera (T00754871)

In this project, we will use two different datasets to study cause-effect analysis and variance analysis.

For cause-effect analysis, the Poison Antidote dataset will be used to examine the effects of different antidotes and poisons on survival time. The study aims to determine the impact of antidote and poison types on survival outcomes while assessing potential interaction effects between these factors. Additionally, we will evaluate which factor (antidote or poison) has the most significant influence on survival time.

The second part of the study focuses on variance analysis using the Acidity of Sour Cream dataset. This analysis will explore whether acidity levels vary significantly across different batches, the position within a batch, or the type of starter culture used. In addition, we will assess whether acidity variance remains consistent across all groups.
